(54) Title: IDENTIFICATION OF NEW THERAPEUTIC TARGETS FOR MODULATING BILE ACID SYNTHESIS

(57) Abstract: Methods for identifying compounds that modulate bile acid synthesis by assessing their ability to act as ligands for short heterodimerizing partner-1 or liver receptor homologue-1 are provided. Also provided are compositions containing these ligands as well as methods for administering these compositions to modulate bile acid synthesis and cholesterol and lipid homeostasis.

IDENTIFICATION OF NEW THERAPEUTIC TARGETS FOR MODULATING BILE ACID SYNTHESIS

5

Field of the Invention

regulatory cascade of three orphan nuclear farnesoid X receptor (FXR), short receptors, 10 heterodimerizing partner-1 (SHP-1), and liver receptor homologue-1 (LRH-1) has now been identified which provides a molecular basis for the coordinate repression of bile acid synthesis and cholesterol and lipid homeostasis. Specifically, it has been found that FXR induces expression 15 of SHP-1 which represses expression of cytochrome P450 7A (CYP7A) by binding to LHR-1. CYP7A catalyzes the rate limiting step in bile acid biosynthesis. The present invention relates to the identification of these receptors as therapeutic targets and the development of ligands 20 targeted to these receptors for use in modulating bile acid synthesis. In particular, the present invention relates to ligands identification of which modulate interaction of SHP-1 and LRH-1. Methods for using these ligands to modulate bile acid synthesis and cholesterol and 25 lipid homeostasis are also provided.

Background of the Invention

Cholesterol is essential for a number of cellular processes, including membrane biogenesis and 30 hormone and bile acid biosynthesis. It is the building block for each of the major classes of lipoproteins found in cells of the human body. Accordingly, cholesterol biosynthesis and catabolism are highly regulated coordinated processes. A number of diseases and/or 35 disorders have been linked to alterations in cholesterol metabolism or catabolism including atherosclerosis, stone formation, and ischemic heart disease. An understanding of the pathways involved in cholesterol homeostasis is essential to the development of useful therapeutics for treatment of these diseases and disorders.

The metabolism of cholesterol to bile acids represents a major pathway for cholesterol elimination from 5 the body, accounting for approximately half of the daily excretion. These cholesterol metabolites are formed in the liver and secreted into the duodenum of the intestine, where they have important roles in the solubilization and absorption of dietary lipids and vitamins. Most bile acids 10 (approximately 95%) are subsequently reabsorbed in the ileum and returned to the liver via the enterohepatic circulatory system.

Cytochrome P450 7A (CYP7A) is a liver specific enzyme that catalyzes the first and rate-limiting step in one of 15 the two pathways for bile acid biosynthesis (Chiang, J.Y.L. 1998. Front. Biosci. 3:176-193; Russell, D.W. and K.D. 1992. Biochemistry 31:4737-4749). Setchell. encoding CYP7A is regulated by a variety of endogenous, small, lipophilic molecules including steroid and thyroid 20 hormones, cholesterol, and bile acids. Notably, CYP7A expression is stimulated by cholesterol feeding repressed by bile acids. Thus, CYP7A expression is both induced) and positively (stimulated or negatively (inhibited or repressed) regulated.

CYP7A expression is regulated by several members of 25 of receptor family ligand-activated nuclear transcription factors (Chiang, J.Y.L. 1998. Front. Biosci. 3:176-193; Gustafsson, J.A. 1999. Science 284:1285-1286; Russell, D.W. 1999. Cell 97:539-542). Recently, 30 nuclear receptors, the liver X receptor (LXR; NR1H3; Apfel, R. et al. 1994. Mol. Cell. Biol. 14:7025-7035; Willy, P.J. et al. 1995. Genes Devel. 9:1033-1045) and the farnesoid X receptor (FXR; NR1H4; Forman, B.M. et al. 1995. Cell 81:687-693; Seol, W. et al. 1995. Mol. Endocrinol. 35 9:72-85) were implicated in the positive and negative regulation of CYP7A (Peet, D.J. et al. 1998. Curr. Opin. Genet. Develop. 8:571-575; Russell, D.W. 1999. Cell 97:539-

Both LXR and FXR are abundantly expressed in the 542). liver and bind to their cognate hormone response elements as heterodimers with the 9-cis retinoic acid receptor, RXR (Mangelsdorf, D.J. and R.M. Evans. 1995. Cell 83:841-850). is activated by the cholesterol derivative 24,25(S)epoxycholesterol and binds to a response element in the CYP7A promoter (Lehmann, J.M. et al. 1997. J. Biol. Chem. 272:3137-3140). CYP7A is not induced in response to cholesterol feeding in mice lacking LXR (Peet, D.J. et al. 10 1998. Cell 93:693-704). Moreover, these animals accumulate massive amounts of cholesterol in their livers when fed a These studies establish LXR high cholesterol diet. cholesterol sensor responsible for positive regulation of CYP7A expression.

Bile acids stimulate the expression of genes involved 15 in bile acid transport such as the intestinal bile acid binding protein (I-BABP) and repress CYP7A as well as other genes involved in bile acid biosynthesis such as CYP8B (which converts chenodeoxycholic acid to cholic acid), and 20 CYP27 (which catalyzes the first step in the alternative "acidic" pathway for bile acid synthesis) (Javitt, N.B. 8:1308-1311; Russell, D.W. FASEB J. Setchell. 1992. Biochemistry 31:4737-4749). Recently, FXR was shown to be a bile acid receptor (Makishima, M. et al. 25 1999. Science 284:1362-1365; Parks, D.J. et al. 1999. Science 284:1365-1368; Wang, H. 1999. Mol. Cell 3:543-553). Several different bile acids, including chenodeoxycholic taurine conjugates its glycine and and demonstrated to bind to and activate FXR at physiologic 30 concentrations. In addition, DNA response elements for the FXR/RXR heterodimer were identified in both the human and mouse I-BABP promoters, indicating that FXR mediates I-BABP expression positive effects of bile acids on (Grober, J. et al. 1999. J. Biol. Chem. 274:29749-29754; 1999. Science 284:1362-1365). 35 Makishima, Μ. et al. Further, the rank order of bile acids that activate FXR correlates with that for repression of CYP7A in a

- 4 -

hepatocyte-derived cell line (Makishima, M. et al. 1999. Science 284:1362-1365). Thus, these studies indicate that FXR also has a role in the negative effects of bile acids on gene expression.

However, the molecular mechanism of bile acidmediated repression of CYP7A, and specifically the role of
FXR has been unclear. Since the CYP7A promoter lacks a
strong FXR/RXR binding site (Chiang, J.Y. and D. Stroup.
1994. J. Biol. Chem. 269:17502-17507; Chiang, J.Y. et al.
2000. J. Biol. Chem. 275:10918-10924), it is unlikely that
the effect is from the direct interaction of FXR.

A ligand which selectively binds and activates FXR has been identified. Using this ligand it has been demonstrated that the human orphan nuclear receptor, FXR, interacts with a nuclear receptor, short heterodimerizing partner-1 (SHP-1). Further, it has now been demonstrated that SHP-1 interacts with LRH-1 to modulate expression of CYP7A. Accordingly, these three receptors are part of a regulatory cascade for coordinate repression of bile acid synthesis and cholesterol and lipid homeostasis.

Summary of the Invention

An object of the present invention is to provide methods for identifying new therapeutic agents which These agents comprise 25 modulate bile acid synthesis. ligands which interact with short heterodimerizing partner-1 (SHP-1) or liver receptor homologue-1 (LRH-1) to modulate expression of genes involved in bile acid synthesis. preferred embodiment of the present invention, the agents 30 comprise ligands which modulate the interaction of SHP-1 Another object of the present invention is with LRH-1. to provide a method for modulating bile acid synthesis in a patient in need thereof which comprises administering to the patient a composition comprising a ligand for short 35 heterodimerizing partner-1 (SHP-1) or liver receptor homologue-1 (LRH-1). In a preferred embodiment, the

- 5 -

composition comprises a ligand which modulates the interaction of SHP-1 with LRH-1.

This technology can thus be used to affect bile acid and cholesterol and lipid homeostasis such that ultimately 5 cholesterol and lipid levels are modified and to treat diseases in which regulation of bile acid, cholesterol and lipid levels is important.

Detailed Description of the Invention

Bile acids are cholesterol metabolites formed in the liver and secreted into the duodenum of the intestine wherein assist in the solubilization and absorption of dietary lipids and vitamins. Thus, bile acids have an in regulating only important role not 15 homeostasis, but also in regulating lipid homeostasis. Modulators of bile acid synthesis can therefore be used in a variety of treatments including, but not limited to, inhibition of fatty acid absorption in the intestine for the treatment of dyslipidemia, obesity and associated 20 diseases including atherosclerosis, inhibition of protein and carbohydrate digestion in the intestine for treatment of obesity, and inhibition of de novo cholesterol biosynthesis in the liver for the treatment of disease including levels cholesterol elevated to related 25 atherosclerosis and gall stones.

Bile acids repress the expression of genes involved in their biosynthesis, including cytochrome P450 7A (CYP7A) which catalyzes the rate limiting step in bile acid biosynthesis. A bile-acid regulatory cascade providing a molecular basis for the coordinate suppression of CYP7A and other genes involved in bile acid synthesis has now been identified. Using a potent, non-steroidal farnesoid X receptor (FXR) ligand, it has been demonstrated that FXR induces expression of short heterodimerizing protein 1 (SHP-1; NRB02), an atypical member of the nuclear receptor family that lacks a DNA binding domain. Further, it has now been demonstrated that SHP-1 represses expression of

- 6 -

CYP7A by binding to the nuclear receptor liver receptor homologue 1 (LRH-1; NR5A2), which binds to a response The interaction of element in the CYP7A gene promoter. SHP-1 and LRH-1 can also result in alterations 5 expression of other genes that these receptors aid regulating, including genes involved in lipid absorption and digestion in the small intestine and lipid homeostasis in the liver. Examples of such genes include, but are not limited to, genes involved in bile acid transport, lipid 10 absorption, cholesterol biosynthesis, proteolysis, acid metabolism, glucose biosynthesis, protein translation, electron transport and hepatic fatty acid metabolism. Thus, the identification of the SHP-1 and LRH-1 receptors being involved in this regulatory cascade serves as a basis 15 for identifying and designing compositions useful in the modulation of bile acid synthesis and cholesterol and lipid homeostasis.

Accordingly, the present invention relates to the identification of ligands specific for SHP-1 or LHR-1 and 20 methods of using these ligands in compositions for the modulation of bile acid synthesis as well as cholesterol In homeostasis and lipid homeostasis. a preferred embodiment of the present invention, the ligands modulate the interaction of SHP-1 with LRH-1. For purposes of "modulate", or invention, by "modulation", 25 present "modulator" it is meant to regulate, adjust or alter physiological conditions or parameters associated with SHP-1 and LRH-1. Thus, examples of modulation include, but are not limited to, the ligand either increasing or decreasing 30 gene expression or activity of the SHP-1 or LRH-1 receptors identified in this biosynthetic cascade for bile acid synthesis, alterations in timing of expression of one or both of these receptors, increases or decrease in bile acid synthesis, and alterations in cholesterol and 35 homeostasis. By the term "ligand" it is meant a compound with the pharmacologic activity to bind to and modulate a receptor in this biosynthetic cascade for bile acid

- 7 -

synthesis. In a preferred embodiment, binding of the ligand to either the SHP-1 or LRH-1 receptor modulates the interaction of SHP-1 with LRH-1.

Ligands for use in the compositions of the present invention can be identified routinely through screening of libraries of compounds using assays such as the FRET assay as described in Parks, D.J. 1999. Science 284:1365-1368 and in WO 00/25134. This assay was used to identify a potent ligand for the FXR receptor. This ligand, referred to herein as GW4064, is depicted in Formula (I):

$$HO_2C$$

$$C1$$

$$C1$$

15 In contrast to bile acids such as chenodeoxycholic acid which bind to FXR with low (micromolar) affinities and interact with other proteins, the potent, selective FXR ligand, GW4064 binds to FXR with an EC50 value of 15 nm. GW4064 also activates rodent and human FXR with EC50 values 20 of 80 and 90 nm, respectively, in CV-1 cells transfected with FXR expression vectors and a reporter driven by two copies of the hsp70 ecdysone receptor response element. Accordingly, this isoxazole of Formula I is 100-fold more potent than chenodeoxycholic acid as an FXR agonist.

25 GW4064 is also highly selective for FXR, activating only the FXR-GAL4 chimera in a panel of nuclear receptor binding assays wherein CV-1 cells were transfected with expression

- 8 -

vectors for various GAL4-nuclear receptor ligand binding domain chimeras and the reporter plasmid (UAS)5-tk-CAT.

Several recent studies have implicated FXR in the repression of CYP7A (Makishima et al. 1999 Science 5 284:1362-5; Parks et al. 1999 Science 284:1365-8, Wang et al. 1999 Molecular Cell 3:543-53). Repression of expression of CYP7A by compounds such as bile acids is known to be part of a regulatory feedback loop that controls the rate of their biosynthesis from cholesterol (Russell, D.W. 1999. Cell 97:539-42; Russell, D.W. and K.D. Setchell, 1992. Biochemistry 31:4737-49). Accordingly, the effects of GW4064 on CYP7A expression were examined.

Treatment of animals with GW4064 was demonstrated to decrease CYP7A levels. Rats treated with GW4064 for 7 days showed a decrease in CYP7A expression levels as compared to vehicle treated rats. This decrease was still measurable despite the fact that the animals had been maintained on a normal light cycle and sacrificed during the daytime when CYP7A levels are known to be quite low. The ability of GW4064 to decrease CYP7A expression in a dose dependent fashion was confirmed in human hepatocytes.

As will be understood by those of skill in the art upon reading this disclosure, additional ligands which are selective for FXR and useful in compositions of the present invention can also be identified in accordance with the procedures described herein. Further, the structure of GW4064 provides a template for the design of new compounds with similar structures also expected to be selective ligands for FXR. Using this structure as a template both agonists and antagonists for FXR can be designed. The selectivity of these new compounds for FXR can be determined routinely by those of skill in the art based upon these teachings provided herein. Like GW4064, newly

- 9 -

identified selective FXR ligands can also be used in the modulation of bile acid biosynthesis.

Using GW4064, SHP-1 has also been identified to be involved in the regulation FXR in the liver. RNA prepared 5 from the livers of rats treated with GW4064 for 7 days exhibited a six-fold increase in SHP-1 expression as compared to RNA from vehicle-treated rats. GW4064 treatment also markedly increased SHP-1 expression in a dose-dependent manner in hepatocytes from both humans and Results from these studies were similar to results from human hepatocytes treated with chenodeoxycholic acid, an endogenous FXR ligand; however, the endogenous ligand was much less potent than GW4064. The reciprocal relationship between regulation of SHP-1 and CYP7A 15 expression, i.e., GW4064 and chenodeoxycholic repressed CYP7A expression at the same concentrations that SHP-1 expression, induction of were required for FXR-mediated induction of SHP-1 being indicative of involved in repression of CYP7A expression. Further, 20 scanning of the mouse, rat and human SHP-1 has revealed the presence of an FXR/RXR binding site within the SHP-1 promoter, which is indicative of the SHP-1 gene being directly regulated by FXR. Direct regulation of SHP-1 by FXR was confirmed in experiments in HepG2 cells transfected 25 with an FXR expression plasmid and reporter plasmids under the control of either the rat or human SHP-1 promoter. Treatment of cells transfected with the FXR expression plasmid and either promoter with GW4064 resulted in a marked induction of reporter activity. In contrast, cells 30 with no FXR or mutations in the SHP-1 promoter for the FXR/RXR binding site showed little to no induction.

Using a mammalian two-hybrid approach, experiments were then performed to determine the ability of SHP-1 to interact with a variety of nuclear receptors implicated in

the regulation of CYP7A. CV-1 cells were transfected with an expression plasmid for a GAL4-SHP-1 chimera, the (UAS) $_5$ tk-CAT reporter, and expression plasmids for chimeras between the strong transcriptional activation domain of 5 VP16 and the isolated ligand binding domains of TR , RXR , RAR , LXR , COUP-TF, HNF4 , and LRH-1. The GAL4-SHP-1 chimera had no activity on its own. Increased reporter activity was detected when GAL4-SHP-1 was co-expressed with in the presence of its ligand 9-cis retinoic acid, RXR 10 demonstrating that this nuclear receptor interacts with SHP-1 in cells in a ligand-dependent fashion. reporter activity was also detected when GAL4-SHP-1 was cotransfected with VP16-LRH-1, activity that was dependent on the presence of GAL4-SHP-1. Accordingly, these data 15 demonstrate that SHP-1 interacts with LRH-1 in cells.

SHP-1 was also demonstrated to play a role in the repression of CYP7A expression. Cotransfection experiments were performed with a rat CYP7A luciferase reporter plasmid containing nucleotides -1573 to +36 of the rat CYP7A 20 promoter, including a conserved LRH-1 binding site. Reporter activity was detected when CYP7A-LUC introduced into HepG2 cells, demonstrating that the CYP7A promoter has basal activity. Cotransfection of increasing amounts of a LRH-1 expression plasmid resulted in a dose-25 dependent increase in reporter activity. The LRH-dependent completely blocked by the reporter activity was cotransfection of SHP-1 expression plasmid. Thus, these data demonstrate that SHP-1 can repress LRH-1-dependent activation of the CYP7A promoter.

Accordingly, compositions comprising ligands for SHP1 can be used in the modulation of bile acid synthesis and
cholesterol and lipid homeostasis. Further, as
demonstrated herein, activation of the CYP7A promoter is
also dependent on LRH-1. Thus, compositions comprising

- 11 -

ligands selective to LRH-1 can also be used to modulate bile acid biosynthesis and cholesterol and lipid homeostasis. In a preferred embodiment of the present invention, the composition comprises a ligand which modulates the interaction of SHP-1 with LRH-1.

Screening of ligands that modulate the SHP-1/LRH-1 interaction can be performed using the mammalian two-hybrid approach described in the preceding paragraph. This approach identifies both SHP-1 modulators and LRH-1 modulators. Alternatively, a FRET-based interaction assay using the LRH-1 ligand binding domain and an interacting peptide from SHP-1 can be employed to identify ligands that modulate the LRH-1/SHP-1 interaction.

Compositions of the present invention comprising a 15 ligand for SHP-1 or LHR-1 can be administered to a patient to modulate CYP7A expression levels, thereby modulating bile acid synthesis and cholesterol homeostasis. which activate FXR transcriptional activity, promote or strengthen the SHP-1/LRH-1 interaction, or inhibit LRH-1 20 transcriptional activity decrease expression levels of CYP7A, thereby modulating the rate of bile acid synthesis. Accordingly, the compositions of the present invention are useful in modulating cholesterol homeostasis as well as lipid homeostasis and in the treatment of diseases and 25 disorders including, but not limited to, atherosclerosis, ischemic heart disease, obesity, and stones, gall dyslipidemia.

Dosing regimes, as well as selection of appropriate routes of administration for the compositions of the present invention can be determined routinely by one of skill in the art based upon in vitro and in vivo data generated in accordance with procedures such as described herein. It is preferred that compositions of the present invention comprise an amount of ligand which is effective

- 12 -

at modulating the synthesis of bile acids. This amount, referred to herein as the "bile acid synthesis modulating amount" can be determined routinely for each identified ligand based upon its activity determined in vitro in human cells and in vivo in animal models. Bile acid modulating amounts can be confirmed in patients in need thereof by monitoring the effects of the ligand on cholesterol and/or lipid levels in the patient. Methods for monitoring cholesterol and lipid levels in a patient are well known and performed routinely by those skilled in the art.

The following non-limiting examples are provided to further illustrate the present invention.

EXAMPLES

15 Example 1: Materials

Chenodeoxycholic acid, dexamethasone, and charcoalstripped, delipidated calf serum were purchased from Sigma
Chemical Co. (St. Louis, MO). DNA modifying enzymes,
polymerases and restriction endonucleases were purchased
from Roche Molecular Biochemicals (Indianapolis, IN).
Charcoal, dextran-treated fetal bovine serum (FBS) was
purchased from Hyclone Laboratories Inc. (Logan, UT). The
human hepatocellular carcinoma cell line HepG2 was obtained
from the American Type Culture Collection (ATCC number HB8065, Manassas, VA). MATRIGEL was obtained from Becton
Dickinson Labware (Bedford, MA). All other tissue culture
reagents were obtained from Life Technologies Inc.
(Gaithersburg, MD).

30 Example 2: Animals

Male Fisher rats were obtained from Charles River Laboratories Inc. (Raleigh, NC) and maintained on a 12 hour light/12 hour dark cycle. Animals were allowed food and chow ad libitum. GW4064 (30 mg/kg) was administered by

- 13 -

gavage twice a day for 7 days and the animals sacrificed by cervical dislocation 4 hours after final treatments. Livers were excised and snap-frozen in liquid nitrogen. Differential gene expression analysis was performed by 5 Curagen Corp. (New Haven, CT).

Example 3: Plasmid Constructs

Expression plasmids for the human nuclear receptor-GAL4 chimeras were prepared by inserting amplified cDNAs 10 encoding the ligand binding domains into a modified pSG5 expression vector (Stratagene, La Jolla, CA) containing the GAL4DBD (amino acids 1 to 147) and the Simian virus 40 large T antigen nuclear localization signal (SV40) (UAS) 5-TK-CAT The ID NO:1). (APKKKRKVG; SEQ 15 (hsp27EcRE)₂-TK-LUC reporter constructs have been previously described (Lehmann et al. 1995. J. Biol. Chem. 270:12953-12956 and Forman, B.M. et al. 1995. Cell 81:687-693, p -actin-SPAP, an expression vector respectively). secreted placental alkaline containing human the 20 phosphatase (SPAP) cDNA under the control of -actin internal control in all promoter was used as an transfections. The expression plasmids for human and mouse FXR (pSG5-hFXR and pSG5-mFXR, respectively) and human SRC-1 have been previously described (Kliewer, S.A. et al. 1998. 25 Cell 92:73-82; Parks, D.J. et al. 1999. Science 284:1365-The full-length coding regions for human LRH-1 (GenBank AB019246) and human SHP-1 (GenBank L76571) were amplified by PCR and cloned into pSG5, creating pSG5-hLRH-1 and pSG5-hSHP-1, respectively. A consensus Kozak sequence 30 was created during amplification. The rat (bases -441 to +19) and human (-572 to +10) SHP-1 promoters were amplified by PCR and the fragments inserted into the BglII site of pGL3-Basic, a promoter-less luciferase reporter vector (Promega, Madison, WI). Site-directed mutagenesis of

- 14 -

putative FXR/RXR binding sites in the rat and human SHP-1 promoters was performed using the Transformer mutagenesis system (Clontech, Palo Alto, CA) with the ratIR1 (bases -321 to -287, 5'-CCTGGTACAGCCTGGaaTAATAtaaCTGTTTATAC-3'; SEQ (bases -304 to -270, NO:2) and humanIR1 CCTGGTACAGCCTGAaaTAATGtaTTGTTTATCC-3'; SEO ID NO:3) Underlined residues are those which have been primers. mutated from the wild-type sequence. Mutated constructs were verified to be free of non-specific base changes by 10 sequencing. pGL3-rCYP7A (-1573/+36) contains bases -1573 to +36 of the rat CYP7A promoter (GenBank Z14108) inserted into the NheI site of pGL3-Basic. VP16-nuclear receptor chimeras contained the 80-amino acid herpes virus VP16 transactivation domain linked to the nuclear receptor 15 ligand binding domain in a modified pSG5 expression vector.

Example 4: Transient Transfection Assays

Transient transfection of CV-1 cells was performed as described previously (Jones, S.A. et al. 2000. 20 Endocrinol. 14:27-39). Typically, transfection mixes contained 2-5 ng receptor expression vector, 20 ng reporter construct, and 8 ng p -actin-SPAP. The amount of DNA used in each transfection was adjusted to 80 ng with carrier plasmid (pBluescript, Stratagene, La Jolla, CA). 25 were maintained for 24 hours in the presence of drug (added as a 1000x stock in dimethyl sulfoxide) in DMEM/F-12 charcoal-stripped, containing 10% nutrient mixture delipidated calf serum. An aliquot of medium was assayed SPAP activity and the cells lysed prior for 30 determination of luciferase expression. Luciferase activities were normalized to SPAP. HepG2 cells were maintained in DMEM/F-12 supplemented with inactivated FBS (Life Technologies, Inc., Gaithersburg, MD). Plasmid DNA was transfected into HepG2 cells using

- 15 -

transfection reagent according to the FuGENE6 manufacturer's instructions (Roche Molecular Biochemicals, Indianapolis, IN). Thus, 24 well culture plates (15 mm diameter) were inoculated with 7 x 10^5 cells 24 hours prior Cells were transfected overnight in 5 to transfection. serum-free DMEM/F-12 with 100 ng reporter construct, 32 ng p -actin-SPAP, and 0-400 ng receptor expression vectors (adjusted to 400 ng with carrier plasmid). Following transfection, the medium was aspirated and the cells 10 cultured for a further 48 hours in DMEM/F-12 supplemented with 10% heat-inactivated FBS. SPAP and luciferase values were determined.

Example 5: Primary Culture of Human and Rat Hepatocytes and Northern Blot Analysis

Primary human hepatocytes and rat hepatocytes (1.5 \times 106 cells) were cultured on MATRIGEL-coated six well plates in serum-free Williams' E medium supplemented with 100 nM penicillin G, 100 100 U/ml dexamethasone, 20 streptomycin, and insulin-transferrin-selenium (ITS-G, Life Technologies, Inc., Gaithersburg, MD). Twenty-four hours after isolation, hepatocytes were treated with either GW4064 (0.1-10 μ M) or chenodeoxycholic acid (1-100 μ M) which were added to the culture medium as 1000x stocks in Control cultures received vehicle 25 dimethyl sulfoxide. alone. Cells were cultured for a further 48 hours prior to harvest and total RNA isolated using a commercially reagent (Trizol, Life Technologies Inc., available MD) according to the manufacturer's Gaithersburg, Total RNA (10 μg) was resolved on a 1% 30 instructions. agarose/2.2 M formaldehyde denaturing gel and transferred to a nylon membrane (Hybond N+, Amersham Pharmacia Biotech Blots were hybridized with 32P-Inc., Piscataway, NJ). labeled cDNAs corresponding to human SHP-1, human CYP7A

15

(bases 99 to 1564, GenBank M93133), mouse SHP-1 (bases 30 to 783, GenBank L76567), or rat CYP7A (bases 235 to 460, GenBank J05460). The SHP-1 cDNA used in these experiments encodes the full-length human SHP-1 protein (amino acids 1-5 260) as described in Seol et al. (1996 Science 272:1336), Subsequently, blots were stripped and reprobed with a radiolabeled -actin cDNA (Clontech, Palo Alto, CA).

Example 6: Electrophoretic Mobility-Shift Assay

Electrophoretic mobility shift assays (EMSA) were 10 performed as previously described (Lehmann, J.M. et al. 1997. J. Biol. Chem. 272:3137-3140). HFXR and hRXR were synthesized from pSG5-hFXR and pSG5-hRXR expression vectors, respectively, using the TNTT7-coupled Reticulocyte 15 System (Promega, Madison, WI). Unprogrammed lysate was prepared using the pSG5 expression vector (Stratagene, La Binding reactions contained 10 mM HEPES, pH Jolla, CA). 7.8, 60 mM KCl, 0.2% nonidet P-40, 6% glycerol, 2 mM dithiothreitol (DTT), 2 μg poly(dI-dC)*poly(dI-dC), and 1 20 μ l each of synthesized hFXR or hRXR . Control incubations received unprogrammed lysate alone. Reactions were preincubated on ice for 10 minutes prior to the addition of [32P]-labeled double-stranded oligonucleotide probe (0.2 pmol). Competitor oligonucleotides were added to the pre-25 incubation at 5, 25 or 75-fold molar excess. Samples were held on ice for a further 20 minutes and the protein-DNA pre-electrophoresed a resolved on complexes polyacrylamide gel in 0.5 X TBE (45 mM Tris-borate, 1 mM room temperature. Gels were dried at EDTA) 30 autoradiographed at -70 C for 1 to 2 hours. The following double-stranded oligonucleotides were used as probes and competitors in EMSA: rSHP, 5'-gatcCCTGGGTTAATAACCCTGT-3' (SEQ ID NO:4); mSHP, 5'-gatcCCTGGGTTAATGACCCTGT-3' (SEQ ID NO:5); hSHP, 5'-gatcCCTGAGTTAATGACCTTGT-3' (SEQ ID NO:6);

- 17 -

mI-BABP, 5'-gatcTTAAGGTGAATAACCTTGG-3' (SEQ ID NO:7); hI-BABP, 5'-gatcCCAGGTGAATAACCTCGG-3' (SEQ ID NO:8); mSHPmut, 5'-gatcCCTGGaaTAATGttCCTGT-3' (SEQ ID NO:9). Underlined residues are those which have been mutated from the wild-5 type sequence.

Example 7: GST Pull-Down Assays

in protein was expressed GST-SHP-1 fusion BL21(DE3)plysS cells and bacterial extracts prepared by one 10 cycle of freeze-thaw of the cells in protein lysis buffer containing 50 mM Tris (pH 8.0), 250 mM KCl, 1% Triton X-100, 10 mM DTT and 1X Complete Protease Inhibitor (Roche Molecular Biochemicals, Indianapolis, IN) centrifugation at 40,000 x g for 30 minutes. Glycerol was 15 added to the resultant supernatant to a final concentration of 10%. Lysates were stored at -80 C until use. [35S]labeled human LRH-1 or mouse pregnane X receptor (PXR), a negative control, were generated using TNT T7-coupled Reticulocyte System (Promega) in the presence of PRO-MIX Biotech Inc., Piscataway, 20 (Amersham Pharmacia Coprecipitation reactions included 25 µl lysate containing GST-SHP-1 fusion protein or control GST, 25 µl incubation buffer (50 mM KCl, 40 mM HEPES, pH 7.5, 5 mM mercaptoethanol, 0.1% TWEEN 20, and 1% non-fat dry milk), 25 and 5 µl [35S]-labeled LRH-SHP-1 or PXR. The mixtures were incubated for 25 minutes with gentle rocking at 4 C prior to the addition of 20 μl glutathione-sepharose 4B beads (Amersham Pharmacia Biotech Inc., Piscataway, NJ) that had extensively washed in protein lysis buffer. Reactions were 30 incubated at 4 C with gentle rocking for an additional 20 The beads were pelleted at 3000 rpm in a minutes. microfuge and washed 4 times with protein incubation Following the final wash, the beads were buffer. resuspended in 25 µl of 2X SDS-PAGE sample buffer

- 18 -

containing 50 mM DTT. Samples were heated to 100 C for 5 minutes and loaded onto 10% Bis-Tris PAGE gel. Autoradiography was performed overnight.

All of the references cited in this application are herein incorporated by reference.

Other objects, features, advantages and aspects of the present invention will become apparent to those of skill in the art from the above description and the following claims. It should be understood, therefore, that the above description including the specific examples as well as the following claims, while indicating preferred embodiments of the invention, are given by way of illustration only. Various changes and modifications within the spirit and scope of the disclosed invention which will become readily apparent to those skilled in the art from reading this disclosure are therefore also encompassed by this application.

What is claimed is:

- A method for identifying compounds that modulate bile acid synthesis comprising assessing the ability of a compound to act as a ligand for short heterodimerizing partner-1 or liver receptor homologue-1, the ability of the compound to act as a ligand for one of these receptors being indicative of the compound being a modulator of bile acid synthesis.
- 10 2. The method of claim 1 wherein the ability of the ligand to modulate the interaction of short heterodimerizing partner-1 with liver receptor homologue-1 is assessed.
- 3. A method for modulating bile acid synthesis in a patient in need thereof comprising administering to a patient a composition comprising a ligand for short heterodimerizing partner-1 or liver receptor homologue-1.
- 20 4. The method of claim 3 wherein the composition comprises a ligand which modulates the interaction of short heterodimerizing partner-1 with liver receptor homologue-1.
- 5. The method of claim 3 wherein the composition 25 comprises a bile acid synthesis modulating amount of ligand.
 - 6. The method of claim 3 wherein cholesterol or lipid homeostasis is modulated.
 - 7. A composition for modulating bile acid synthesis comprising a ligand for short heterodimerizing protein-1 or liver receptor homologue-1.

30

- 20 -

- 8. The composition of claim 7 wherein the ligand modulates the interaction of short heterodimerizing protein-1 with liver receptor homologue-1.
- 9. The composition of claim 7 comprising a bile acid synthesis modulating amount of ligand.

(54) Title: IDENTIFICATION OF NEW THERAPEUTIC TARGETS FOR MODULATING BILE ACID SYNTHESIS

(57) Abstract: Methods for identifying compounds that modulate bile acid synthesis by assessing their ability to act as ligands for short heterodimerizing partner-1 or liver receptor homologue-1 are provided. Also provided are compositions containing these ligands as well as methods for administering these compositions to modulate bile acid synthesis and cholesterol and lipid homeostasis.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

Continuation of Box I.1

Although claims 3-6 are directed to a method of treatment of the human body, the search has been carried out and based on the alleged effects of the composition.

Continuation of Box I.1

Claims Nos.: 3-6 (partially)

Rule 39.1(iv) PCT - Method for treatment of the human or animal body by therapy

Continuation of Box I.2

Claims Nos.: 7-9 (partially)

Present claims 7-9 relate to a substance and its use defined by reference to a desirable characteristic or property, namely a modulator of bile acid synthesis comprising a ligand for short heterodimerizing protein-1 or liver receptor homologue-1.

The said claims cover all substances having this characteristic or property, whereas the application provides support within the meaning of Article 6 PCT and/or disclosure within the meaning of Article 5 PCT for only GW4064. In the present case, the claims so lack support, and the application so lacks disclosure, that a meaningful search over the whole of the claimed scope is impossible. Independent of the above reasoning, the claims also lack clarity (Article 6 PCT). An attempt is made to define the substances by reference to a result to be achieved. Again, this lack of clarity in the present case is such as to render a meaningful search over the whole of the claimed scope impossible.

The applicant's attention is drawn to the fact that claims, or parts of claims, relating to inventions in respect of which no international search report has been established need not be the subject of an international preliminary examination (Rule 66.1(e) PCT). The applicant is advised that the EPO policy when acting as an International Preliminary Examining Authority is normally not to carry out a preliminary examination on matter which has not been searched. This is the case irrespective of whether or not the claims are amended following receipt of the search report or during any Chapter II procedure.

International application No. PCT/US 01/24203

INTERNATIONAL SEARCH REPORT

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)
This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:
1. X Claims Nos.: 3-6 (partially) because they relate to subject matter not required to be searched by this Authority, namely: see FURTHER INFORMATION sheet PCT/ISA/210
2. X Claims Nos.: 7-9 (partially) because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
see FURTHER INFORMATION sheet PCT/ISA/210
3. Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).
Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)
This International Searching Authority found multiple inventions in this international application, as follows:
As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:
Remark on Protest The additional search fees were accompanied by the applicant's protest. No protest accompanied the payment of additional search fees.
